Preliminaries - Kyber

In this work, we present an attack on Kyber using the combination of a chosen-ciphertext attack and a single-bit fault attack.

- ▶ Kyber is a CCA2-secure post-quantum KEM.
- ▶ Finalist in the NIST standardization process.
- ▶ Relies on the hardness of the MLWE problem (lattice-based).
- ▶ Three parameter sets: Kyber512, Kyber768, Kyber1024.
- ▶ Built from an underlying PKE using a variant of the FO-transform.
- ▶ Works in $R = \mathbb{F}_q[x]/(x^n - 1)$ and R^k .

Kyber - Decapsulation

During decryption, the message is recovered from the polynomial¹

$$\begin{aligned} rec &= m + \mathbf{e}^T \mathbf{r} - \mathbf{s}^T \mathbf{e}_1 + e_2 \\ &= m + noise. \end{aligned}$$

where \mathbf{e}, \mathbf{s} are secret, other terms are known to the attacker².

¹Coefficients in $\{0, \dots, q-1\}$; Ignoring compression errors

²Vectors of polynomials in bold

Kyber - Message recovery

- Encryption: 0-bits mapped to 0, 1-bits mapped to $\frac{q}{2}$ (one bit to one coefficient).
- Decryption: Recover from $rec = m + noise$ by mapping to 0 if closer to 0 than to $\frac{q}{2}$, otherwise to 1.
- Upper half of the circle mapped to 0, lower half to 1.

Decryption errors

- ▶ Message is recovered from $rec = m + noise$.
- ▶ Adding $\frac{q}{4}$ to a coefficient of rec : Corresponding message bit might change depending on which side the noisy message is on.
- ▶ Decryption error happens if $noise$ coefficient is positive.

Decryption errors

- ▶ Adding $\frac{q}{4}$ and observing decryption errors tells us if a coefficient of

$$\text{noise} = \mathbf{e}^T \mathbf{r} - \mathbf{s}^T \mathbf{e}_1 + e_2.$$

is positive or negative³.

- ▶ Gives inequalities involving secrets \mathbf{e}, \mathbf{s} .

³Ignoring compression errors

Pessl and Prokop's attack

A recent fault attack by Pessl and Prokop takes advantage of decryption errors.

- ▶ Pessl and Prokop fault the decoder to cause the addition of $\frac{q}{4}$.
- ▶ From each fault/decapsulation: Recover one inequality.
- ▶ Solve inequalities by updating distributions of coefficients using obtained inequalities.

Several limitations:

- ▶ Prevented by shuffling.
- ▶ Very specific fault model.
- ▶ Depends on the implementation.

Our attack

- ▶ Send manipulated ciphertext c' with $\frac{q}{4}$ added to one coefficient of a valid ciphertext c .
- ▶ Device under attack obtains c'' from re-encryption.
- ▶ After decryption, fault one bit of stored ciphertext c' to match c .
- ▶ Thereby, the FO-transform effectively compares c against c'' .
- ▶ Observe decryption errors and obtain inequalities.

Our attack

By introducing the fault

- ▶ The device decrypts c' , which is c with a $\frac{q}{4}$ -error added in one coefficient.
- ▶ Result of re-encryption c'' is compared against c (as c' was corrected).

Two cases:

1. c' causes decryption error \Rightarrow decrypt returns $m' \neq m \Rightarrow c'' \neq c$.
2. c' causes no decryption error \Rightarrow decrypt returns $m' = m \Rightarrow c'' = c$.

Fault model

Fault location in time:

- ▶ After decrypt was called,
- ▶ and before the re-encryption comparison.

Value to be faulted:

- ▶ Either the stored ciphertext,
- ▶ or the ciphertext obtained from re-encryption.

Fault model: Set, reset, or flip a single bit.

Solving inequalities using belief propagation

Using belief propagation needs 20-30% less faults and requires significantly less RAM.

- ▶ For each unknown coefficient of x (given by \mathbf{e} and \mathbf{s}), we initialise a *variable node* with a prior given by the binomial distribution they were sampled from.
- ▶ For each inequality, we initialise a *check node*.

Advantages

Our approach: Instead of sending a valid ciphertext and then applying a fault, send manipulated ciphertext and use a fault to correct.

Several advantages:

- ▶ Manipulation is performed offline, therefore observing successful decapsulation means that the fault worked (even with unreliable faults).
- ▶ Not prevented by shuffling the decoder and several other countermeasures.
- ▶ Fault may be introduced at several places in time/memory over a very long time-span.
- ▶ Less implementation specific.

Performance - Success rate

Performance - Runtime

Runtimes in minutes on a Intel(R) Xeon(R) Gold 6242 with 32 and 8 threads.

Parameter set	Iterations	32 threads	8 threads
Kyber512 (6000 inequalities)	6.8	3.25	9.3
Kyber768 (7000 inequalities)	6.75	6.7	18.6
Kyber1024 (9000 inequalities)	9	16.9	39.25

Thank you for listening!
